## 1.0 INTRODUCTION

### 1.1 Study Objectives and Location

This Functional Servicing and Stormwater Management Report has been prepared in support of a proposed residential subdivision development located east of Trafalgar Road in the Town of Erin (Formerly the Village of Hillsburgh), County of Wellington. The site can be legally described as being located within Concession 8, Registered Plan 95, with the following parts:

- Part of Lots 23 & 24 (Concession 8),
- Part of Lots 11 & 12 (East of Market Street),
- Part of Lots 14, and all of Lots 15 & 16 (West of Market Street);
- Part of Lots 4 & 17, and all of Lots 18, 19, & 20 (East of Guelph Street);
- Part of Lots 21 & 22, and all of Lots 23 & 24 (West of Guelph Street).

The subject property is located within the boundaries of Douglas Crescent to the north, Trafalgar Road to the West (also known as Main Street and Wellington Road 24), 8<sup>th</sup> Line to the east and Wellington Road 22 to the south. A site location plan is provided in Figure 1-1.

The following report provides information regarding site servicing and stormwater management for the subject development while ensuring compatibility with surrounding lands. The report will also address concerns and comments raised by regulatory agencies (i.e., County of Wellington, Credit Valley Conservation Authority, and the Town of Erin).

### 1.2 Existing Conditions

The site is irregular in shape covering a total area of approximately 52.3 ha. Currently the site is predominantly used for agricultural purposes. A single lot, referred to as the “Heritage house” (Block 504), is to remain untouched through the proposed development. In general, the site can predominantly be accessed via Trafalgar Road. The eastern side of the site (furthest from Trafalgar Road) contains the highest elevations, sloping downwards toward the west. Existing access points include an entrance from the existing termination point of Curie Road to the north. The site also fronts the existing Ross R. Mackay Public School, as well as some commercial properties situated along Trafalgar Road. Existing detached homes are present just adjacent to the property and front Trafalgar Road. At the time of writing external lands to the south and east of the site consist entirely of farmland. Lastly, the Elora Cataract Trail straddles the southwest corner of the site, creating a physical separation from the Trafalgar Road right of way.

### 1.3 Proposed Development

The proposed development is to include a mix of residential townhouse blocks, single-detached homes, park land, retirement living (i.e., senior's homes) in the form of low density and mixed-use apartments, as well as dedicated stormwater management (SWM) blocks. The proposed subdivision lands will be provided transportation access via site entrances on Trafalgar Road, Spruce Street and Currie Road. Connectivity with potential future developments to the east and south will also be accommodated with proposed dead-end roads at the northeastern and southern site boundaries. The proposed site's development plan is shown in Figure 1-2.

### 1.4 Proposed Design Populations

Based on the current development draft plan, a mix of unit densities are proposed. The following table summarizes the anticipated design populations for each land use and was estimated based on the Town of Erin's latest Engineering Design Criteria. Based on the estimate below, the total proposed design population considered for the Hillsburgh Subdivision is 2976 persons.

**Table 1-1: Population Estimate**

| Land Use                             | G.F.A (sqm) / Units                                | Population Density | Design Population* |
|--------------------------------------|----------------------------------------------------|--------------------|--------------------|
| Residential                          | 376 units **<br>(Single-Detached & Heritage House) | 2.8 persons / Unit | 1053               |
| Residential                          | 286 units **<br>(Townhouse)                        | 2.8 persons / Unit | 801                |
| Low-Rise Senior Housing Block 424    | 136 units *<br>(Townhouse)                         | 2.8 persons / Unit | 381                |
| Mixed-Use Senior Apartment Block 423 | 2.24 ha                                            | 330 persons / ha   | 741                |
| Institutional (Schools)              | 0 m <sup>2</sup>                                   | 60 persons / ha    | 0                  |
| Commercial (Retail)                  | 0 m <sup>2</sup>                                   | 100 persons / ha   | 0                  |
| <b>Total Design Population</b>       | <b>798</b>                                         | <b>-</b>           | <b>2976</b>        |

\*Population and unit estimates are based on the population densities set out by the Town of Erin Engineering design guidelines. The resulting populations have been used for engineering design capacity purposes only, and therefore may not be consistent with proposed planning populations for the development.

\*\*Unit Count based on the latest Draft Plan.

- Credit Valley Conservation (CVC), *Stormwater Management Criteria*, dated August 2012;
- CVC / TRCA, *Low Impact Development Stormwater Management Planning and Design Guide*, dated 2010.
- Ministry of the Environment, *Stormwater Management Planning and Design Manual*, dated March 2003.
- Soil Engineers Ltd., *A Preliminary Hydrogeological Assessment for Proposed Residential Development, 63 and 63A Trafalgar Road, Town of Erin*, dated February 2023;
- Soil Engineers Ltd., *Pre- and Post-Development Water Balance Assessment, Proposed Residential Development, 63 and 63A Trafalgar Road, Town of Erin*, dated March 2023;
- Town of Erin, *Engineering Design Standards Manual*, dated May 2022;

## **2.0 Stormwater Management**

### **2.1 Existing Conditions**

#### **2.1.1 Topography and Drainage**

The subject development is part of the larger drainage area of the Credit River's Subwatershed 15, also known as the West Credit River Subwatershed, as identified within the CVCA's Design Criteria. In general, existing site grades indicate an east to west drainage pattern taking overland runoff from the east portion of the site towards Trafalgar Road. Existing site drainage which reaches Trafalgar Road is conveyed by a series of sewers and culvert crossings. These crossings carry runoff flows further west towards the existing naturally occurring ponds north and south of Station Drive. In the site's southwest corner, a 600 mm diameter culvert crossing is present which allows for site drainage across the Elora Cataract Trailway, towards the existing Trafalgar Road minor storm sewer system. Flows from the minor system drain to the existing watercourse to the west via an existing outfall along Jane Street.

Existing topography indicates an existing grade differential in the order of 20 m across the site, with the highest point (elevation 451.63 masl) located at the eastern most corner of the site. The lowest existing grades are present along the property's frontages to Trafalgar Road. The elevation on site is 426.92 masl, measured adjacent to the existing Elora Cataract Trailway at the southern most corner of the site.

It should be noted that a total external drainage area of approximately 48 ha flows towards the site from the west. This area is currently used for agricultural purposes and includes some wooded areas. Based on available topographic information, the external area was characterized as two (2) distinct catchments and have been depicted on Figure 2-1 (Part 2).

#### **2.1.2 Existing Storm Drainage Infrastructure**

Reference drawings provided by the County of Wellington and the Town of Erin were used to identify the following stormwater infrastructure in proximity to the site:

- A 250 mm diameter storm sewer runs South along Trafalgar Road, connecting to the existing 300 mm diameter storm sewer on Jane Street, terminating at an existing 525 mm diameter outfall West of Trafalgar;
- A 250mm diameter storm sewer runs south along Trafalgar Road, outleting to a 600 mm diameter storm sewer, and subsequent headwall within an easement just west of Ross R. McKay School;

- A 1.0 m by 1.8 m CSP culvert crossing beneath Trafalgar Road, from the subject site to an outlet located at the head of a ditch along the south boulevard of Station Street.;

All the above infrastructure was identified to ultimately convey flows west to the existing Credit River watercourse, as part of the West Credit River watershed. No other storm infrastructure was identified on or near the site. This existing infrastructure in proximity to the site is shown schematically on Figure 2-1.

### 2.1.3 Soil Conditions

Sub-surface conditions on the site were initially determined using the Ontario Soil Survey of Wellington County, Soil Survey Report No. 35, produced by the Canadian Department of Agriculture in 1962. Based on the soil map, the site soils can be defined as Hillsburgh Sandy Loam to Fine Sandy Loam. This soil typically has higher percolation rates which is often a good material to support infiltration-based LID techniques on-site, noted as having “Good” drainage characteristics. In-situ soil conditions (soil percolation and seasonal groundwater elevations) will be measured by the site soil engineer to confirm the properties of site soils once proposed LID locations and depths are finalized at the detailed design stage.

A Preliminary Hydrogeological Assessment of the site was produced by Soil Engineers Ltd., dated January 2023. As part of the investigation a series of boreholes and groundwater monitoring wells were installed on-site. Based on the results of the monitoring period, groundwater elevations were found to range between 2.75 to 6.1 mbgs, consistent with elevations of 423.70 to 440.74 masl. Based on the field investigations, soil types on-site ranged from Sand/gravelly sand near surface to a Sandy Silt/Silty Sand Till at greater depths and are considered to be favourable for potential infiltration-based LIDs. The soil types found in this investigation are consistent with the expectations provided by the Ontario Soil Survey mappings of the area. Relevant excerpts from the site hydrogeological report are provided in Appendix A.

## 2.2 Stormwater Management Design Criteria

The stormwater management design criteria applicable to the proposed development was established through a review of regulatory agency design standards. The relevant stormwater management design criteria and regulatory bodies are summarized in this section.

### **Credit Valley Conservation Authority (CVCA) Criteria**

- Quantity Control – Post to pre-development peak flow controls (2-year through 100-year return frequency) for proposed developments within Sub-watershed 15 of the Credit River.

- Quality Control - Enhanced (Level 1) water quality protection (80% TSS removal).
- Erosion Control - Minimum retention of the first 5mm of rainfall volume for erosion control and water balance mitigation.
- Water balance – A site specific water balance is required to identify pre-development groundwater recharge rates and distribution, as well as related hydrologic and ecologic functions. Pre-development groundwater recharge rates must be maintained, and appropriate mitigation measure put in place to ensure the protection of existing hydrological and ecological features.

### **Town of Erin**

- Quantity Control - Post-development runoff at the proposed discharge location shall be limited to within the receiving sewer. The minor conveyance system shall be sized to convey a minimum 10-year return period event.
- Storm Distributions – SWM Facility volumes shall be estimated using the worse of the 24hr SCS Type II storm (required for sites within the West Credit River Subwatershed), and the 4hr Chicago design storm distribution.
- Rainfall intensities should be derived from the Town's IDF curve information as presented in the following table:

**Table 2-1 Town of Erin IDF Curve Parameters**

| RETURN PERIOD | A    | B    | C     |
|---------------|------|------|-------|
| 2-Year        | 566  | 1.77 | 0.730 |
| 5-Year        | 744  | 1.76 | 0.729 |
| 10-Year       | 869  | 1.79 | 0.730 |
| 25-Year       | 1011 | 1.75 | 0.728 |
| 50-Year       | 1126 | 1.76 | 0.729 |
| 100-Year      | 1248 | 1.83 | 0.732 |

*\*Values as per the Town of Erin 2022 Design guidelines.*

The average rainfall intensity shall be calculated using the equation:

$$\left( i = \frac{A}{(t + B)^C} \right)$$

### **Source Water Protection**

In addition to the standards set out by the Town of Erin's design criteria and the CVCA, it is also known that a portion of the site will be located in a future Well Head Protection Area (WHPA). In accordance with comments received from Wellington Source Water Protection staff (WSWP), a WHPA-A will be designated in the future, corresponding with the location of the new drinking water well at the northeast limit of the development.

In accordance with Policy SWG-13 for WHPA-A's and correspondence with WSWP staff, no stormwater infrastructure which discharges or infiltrates into the ground should be located within a 100-meter radius of the future well (see Figure 2-3). As such no Low-Impact Developments or storm outlets will be proposed in this area.

Furthermore, all storm sewers located within this area shall follow higher construction standards and inspection protocols by the owner in order to minimize and eliminate leaks. The specific standards to be applied in this development will be confirmed with the Issuing Director of Environmental Compliance Approval for these sewers at a later stage of the project.

## **2.3 Proposed Site Grading and Drainage**

In the site's existing conditions, a significant grade differential exists, in the order of 20 m from east to west. In order to mimic site pre-development drainage conditions, it is proposed to maintain positive drainage from east to west such that the proposed development grades towards Trafalgar Road.

Proposed grading for the site promotes sheet flow drainage away from proposed townhomes and detached lots and towards overland flow routes provided by internal roadways. The maximum proposed paved surface grades have been held below 8%, with landscaped areas held at a minimum 2%. The site's grading in relation to the proposed SWM Plan is discussed in the following sections. A functional site grading plan has been provided in Appendix E for details.

## **2.4 Proposed Stormwater Management Plan**

The proposed stormwater management system will be designed in accordance with Town of Erin and CVCA guidelines. The intent of the design is to maintain existing drainage conditions to the extent possible, while adhering to the quantity control criteria set out by both the Town of Erin and

CVCA criteria.

In order to better mimic existing stormwater drainage patterns on-site, it is proposed to split site drainage into two catchments: North (01) and South (02). Each of these catchments will be serviced by their own respective SWM facilities, located within each of the site's two (2) SWM Blocks. These ponds have been identified as follows:

1. SWM Pond 1 – North Pond located in SWM Block 426
2. SWM Pond 2 – South Pond located in SWM Block 425

Each SWM Block will include both a SWM Pond and a downstream bioretention cell. SWM Pond will be sized and equipped with an outlet structure in order to control site post-development peak flows to pre-development levels for each storm event up to and including the 100-year event.

Conveyance of stormwater to each pond will be managed by a dual-drainage system consisting of (1) a minor storm sewer system which will capture and convey minor storm events and (2) a major system consisting of overland flow routes along the proposed roadways. The major system has been designed to direct overland flows to a couple of key low points (see Figure 2-2) from which flows will be captured by catchbasins and conveyed to the nearest SWM Pond through the minor system.

Water quality control is proposed primarily via end-of-pipe permanent pools, or wet cells, provided within each of the two proposed SWM Pond facilities. Each pond's permanent pool has been sized to provide a minimum 80% TSS removal based on the MOE 2003 criteria, for each pond's incoming drainage area. Infiltration trenches are expected to provide additional water quality control and groundwater recharge at source. Lastly, bioretention swales downstream of each SWM pond will provide additional infiltration potential prior to discharging flows off-site. The following sections discuss the proposed SWM Plan in detail.

## **2.5 Quantity Control**

In accordance with the Town of Erin and CVCA design criteria, it is proposed to control site post-development flows to match pre-development levels for all storm events up to and including the 100-year event. Storm events will be analysed for the 24-hour SCS and 4hr Chicago storm distributions in accordance with Town and CVC standards. In order to do so, pre-development flow rates have been estimated for each of the pre-development catchments depicted in Figure 2-1.

### 2.5.1 Pre-development and External Flows

In addition to the subject site area, a pre-development flow estimate was conducted for the approximately 48 hectares of external lands which drain from east of the subject site. Flows from this area will be accepted and captured by the subject development's storm drainage system in order to maintain existing drainage patterns. As such the proposed SWM Pond controls have incorporated the pre-development flows of external areas. External Catchments 10 and 20 are shown on Figure 2-1 for reference.

It should be noted that when external lands are re-developed, future developments will need to provide site level controls such that they control runoff flows from storm events up to and including the 100-year storm event to pre-development levels. This will allow future developments to remain compatible with the proposed SWM Pond facilities.

The pre-development flow rates for each catchment were determined using a pre-development hydrology model developed using Visual OTTHYMO (VO) Version 6.2. In order to assess the flows for each catchment, a pre-development Nashyde node was created for each catchment with parameters including those describing soil type, landcover quality and time of concentration. Times of concentration for the external area were determined using the Bransby-William's method with flow paths depicted in Figure 2-1. Soil covers complex numbers (i.e. CN numbers) were determined for each catchment based on land cover type. Detailed calculation of these input parameters is provided in Appendix B, alongside the associated VO model output. A summary of the pre-development peak flow rates is presented in Table 2-2 and Table 2-3.

**Table 2-2: Summary Pre-development Peak Flows (24-hour SCS)**

| Return Period | Pre-Development Peak Flow – 24-hour SCS |                                 |                            |                                 |                                |                            |

## 2.5.2 Post Development

The peak flows presented in Table 2-2 and 2-3 represent the expected peak flows draining to each of the two existing site outlets. This includes Catchment 01 draining to the 1.0 m x 1.8 m CSP culvert, and Catchment 02 draining to the existing 600 mm diameter CSP culvert. In summary the allowable release rate to each existing site outlet has been split between the northern and southern SWM blocks such that:

- Post-development peak flows from North SWM Block 426 = Pre-development flows from Predevelopment Catchment 01 + External Catchment 10
- Post-development peak flows from South SWM Block 425 = Pre-development flows from Pre-development Catchment 02 + External Catchment 20

As shown in the comparison of the pre-development flows in Table 2-2 and Table 2-3, between the 4-hour Chicago and 24-hour SCS it is estimated that peak flows from the 24-hour SCS storm are greater for the site. In order to ensure both storm distributions are safely detained, the 2-year through 100-year events were simulated using VO in the post-development condition. Each SWM Pond has been sized to satisfy whichever event requires the largest detention volume.

In the post-development condition, the site area is proposed to be graded such that it forms two (2) post-development catchments, Catchments 01 and 02, as depicted in Figure 2-2, which will drain to SWM Pond 1 and 2 respectively. The site's post-development land-use was then used to

estimate the site's impervious levels and used as input to simulate the post-development peak flows. Post-development imperviousness estimates are provided in Appendix B.

In addition, a portion of the site adjacent to Trafalgar Road was unable to be directed back to the SWM Ponds due to site grading constraints. As a result, uncontrolled flows are also anticipated from Catchments 101 and 201, which drain to the North and South outlet respectively. These catchments are depicted in Figure 2-2. A summary of the uncontrolled flows from each catchment are summarized in Table 2-4 and Table 2-5.

Each pond's target release rate was established by taking the pre-development flows presented in Table 2-2 and Table 2-3, and reducing them by the estimated uncontrolled flows from catchments 101 and 201. This ensures that the total uncontrolled and controlled flows from the site do not exceed the pre-development flow level to each outlet. The adjusted target rates are summarized in Table 2-4 and 2-5. A summary of the resulting required storage volumes for each SWM Block and storm distribution is provided in Table 2-6 and Table 2-7.

**Table 2-4: Summary of Release Rates – Pond 1 (North)**

| Storm Distribution | 24-hour SCS         |                               |                     | 4-hour Chicago      |                               |                     |
|--------------------|---------------------|-------------------------------|---------------------|---------------------|-------------------------------|---------------------|
|                    | Pre-Dev. Peak Flow  | Node 101 Uncontrolled Release | Controlled Release  | Pre-Dev. Peak Flow  | Node 101 Uncontrolled Release | Controlled Release  |
|                    | (m <sup>3</sup> /s) | (m <sup>3</sup> /s)           | (m <sup>3</sup> /s) | (m <sup>3</sup> /s) | (m <sup>3</sup> /s)           | (m <sup>3</sup> /s) |
| 2-yr               | 1.311               | 0.104                         | 1.207               | 0.930               | 0.169                         | 0.761               |
| 5-yr               | 1.777               | 0.124                         | 1.653               | 1.672               | 0.247                         | 1.425               |
| 10-yr              | 2.987               | 0.180                         | 2.807               | 2.263               | 0.300                         | 1.963               |
| 25-yr              | 3.922               | 0.224                         | 3.698               | 3.090               | 0.362                         | 2.728               |
| 50-yr              | 4.735               | 0.244                         | 4.491               | 3.753               | 0.409                         | 3.344               |
| 100-yr             | 5.152               | 0.277                         | 4.882               | 4.420               | 0.454                         | 3.966               |

As per Table 2-6 and Table 2-7, the maximum storage volume requirement for each SWM Pond is expected to occur during the 100-year, 4-hour Chicago storm event. As such, each facility has been sized to accommodate the event which requires the greatest storage volume to detain; the 100-year 4-hour Chicago Storm.

Furthermore, it should be noted that during the 24-hour SCS storm, flows are anticipated to be

much greater than during the 4-hour Chicago event. Due to the quantity of these flows, care was taken to ensure that existing downstream infrastructure has capacity to safely convey runoff flows from the site. The findings of this investigation are discussed in detail within Section 2.3.5 of this report.

| 25-yr              | 1.686               | 0.121                         | 1.565               | 1.328               | 0.197                         | 1.131               |
| 50-yr              | 2.019               | 0.131                         | 1.888               | 1.612               | 0.222                         | 1.390               |
| 100-yr             | 2.211               | 0.146                         | 2.065               | 1.903               | 0.246                         | 1.657               |

It was found that controlling to pre-development flow rates for SWM Pond 1 during the 24-hour SCS distribution results in capacity exceedances in the 50-year and 100-year event. To avoid this issue, it is proposed to overcontrol these two events to within the capacity of the downstream storm sewer system. This is reflected in the 50-year and 100-year storage estimates in Table 2-6.

**Table 2-6: Summary of Required Storage Volumes – SWM Pond 1 (North)**

| Storm Distribution | 24-hour SCS         |                     |                   | 4-hour Chicago      |                     |                   |
|--------------------|---------------------|---------------------|-------------------|---------------------|---------------------|-------------------|
| Return Period      | Pre-Dev. Peak Flow  | Controlled Flow     | Required Storage  | Pre-Dev. Peak Flow  | Controlled Flow     | Required Storage  |

| 25-yr              | 1.686                                     | 1.565                                  | 7575                                  | 1.328                                     | 1.131                                  | 8650                                  |
| 50-yr              | 2.019                                     | 1.888                                  | 8520                                  | 1.612                                     | 1.390                                  | 9530                                  |
| 100-yr             | 2.211                                     | 2.065                                  | 8920                                  | 1.903                                     | 1.657                                  | 10380                                 |

Note that the final storage volume requirements for each SWM Pond will be further refined and confirmed at the detailed design stage. The preliminary design of each SWM Pond is shown in the Functional Servicing and Grading Drawings provided in Appendix E.

## 2.6 Water Quality Control

As per the Town of Erin and CVCA design criteria, site runoff must be treated to meet an enhanced level of quality control (removal of 80% TSS). The proposed site will consist of both clean roof area and landscape area, as well as a drivable laneway area. In order to provide treatment to an enhanced level, a treatment train is proposed for each of the site's drainage areas. The proposed treatment train consists of the following components:

- **End of Pipe Controls** – SWM Pond Wet Cells sized to provide 80% (Enhanced) TSS removal, and Bioretention feature sized to provide a minimum 60% (Basic) TSS removal located directly upstream of the site's outlets;
- **Lot Level Controls** – Reduction of lot slopes, and rear-yard infiltration trenches;
- **Conveyance Controls** - OGS units sized to provide a minimum 50% TSS removal to the site area in line with the site's conveyance system (i.e., storm sewers);

The combination of the above LIDs is expected to provide a net 80% TSS removal to achieve the target enhanced level of water quality treatment.

### 2.6.1 SWM Pond Wet Cell

The primary mechanism for providing quality treatment on-site will be through the use of centralized wet cells (or permanent pools) within each of the two (2) proposed SWM Ponds. These permanent pools have been sized to provide an enhanced level of quality controls (80% TSS removal) on their own to incoming flows based on MOE 2003 guidelines, Table 3.2 for wet ponds. The preliminary sizing of each SWM Pond's permanent pool is summarised in Table 2-8 below. Required volumes will be refined and confirmed at the detailed design stage.

**Table 2-8: Summary of Permanent Pool Sizing's**

| Area ID | Incoming Area (ha) | Imp. (%) | Required Water Volume (m <sup>3</sup> /ha) * | Required Permanent Pool Volume (m <sup>3</sup> ) | Provided Permanent Pool Volume (m <sup>3</sup> ) |
|---------|--------------------|----------|----------------------------------------------|--------------------------------------------------|--------------------------------------------------|
| 01 + 10 | 71.83              | 28%      | 130                                          | 6446                                             | 6500                                             |
| 02 + 20 | 27.25              | 51%      | 180                                          | 3815                                             | 4390                                             |

\*Calculations provided in Appendix B, determined for Wet Ponds as per MOE 2003 Table 3.2, with a 40 m<sup>3</sup> / ha reduction for extended detention storage.

### 2.6.2 Bioretention Cell and Infiltration Trenches

Unconventional mechanisms of quality treatment, such as the Bioretention cells and infiltration trenches are considered to provide additional quality treatment above the Town's requirements, although for the purposes of the proposed design, these methods are proposed more for their ability to provide on-site infiltration. As such the function of these auxiliary measures are proposed more as a method of providing water balance and erosion control on-site.

The bioretention cells will be provided downstream of the proposed SWM Pond outlets, acting as an infiltration basin, and will provide a meandering low flow channel to allow for a by-pass to the existing site outlet, in the event of larger storm events. A preliminary bioretention sizing is provided in Appendix B.

Furthermore, preliminary infiltration calculations were performed based on the anticipated soil performance (see Appendix B), as indicated by Soil Engineer's preliminary hydrogeological investigation, dated January 2023. The final LID design will be informed by in-situ site testing to confirm a suitable design infiltration rate, and depth of the groundwater table, in order to achieve a maximum 48-hour drawdown time, and minimum 1.0 m spacing from the LID to the groundwater table. This will be done at the detailed design stage once proposed LID locations and depths are confirmed.

### **2.6.3 OGS Unit**

Lastly, due to grading constraints along Street '1', a stretch of roadway near the site's connection to Trafalgar Road will be unable to be directed to proposed SWM Pond 1. As a best effort, as much area as possible has been proposed to be captured within storm sewers and directed to an OGS unit located within the SWM Block, and discharge flows just downstream of SWM Pond 1.

At the time of writing the anticipated service area of this OGS is approximately 0.30ha. This unit will be sized to provide a minimum 60% TSS removal to incoming flows. Flows directed to this unit will be able to be conveyed to the proposed bioretention cell, where they will receive additional treatment. It is anticipated that the proposed treatment train of an OGS units and downstream bioretention cell will provide an enhanced level of treatment to these uncontrolled flows prior to being discharged off-site. Sizing of the OGS unit, and the expected feasible treatment rate of the uncontrolled area will be confirmed at the detailed design stage.

The preliminary location of the aforementioned LIDs is shown on the preliminary engineering drawings provided in Appendix E and schematically in Figure 2-3. Locations and sizing of each LID will be confirmed at the detailed design stage.

## **2.7 Erosion Controls and Water Balance**

### **2.7.1 Erosion Control**

In accordance with the CVCA requirements, the implementation of LID practices within the development should provide on-site retention of the first 5 mm of rainfall from the future development's impervious surfaces. The runoff volume requirements for a 5 mm rainfall event within each post-development catchment was estimated and is summarized in Table 2-9.

The proposed site land cover will be a mix of paved and pervious surfaces as well as clean roof area. The pervious landscape areas, particularly those within proposed pervious backyard areas, provide opportunity to promote infiltration. Furthermore, the on-site woodlots, blocks 436 and 437, will continue to provide retention and abstraction of runoff as they will remain undisturbed by the development, and therefore limit the impact on infiltration volumes.

In order to meet the site's 5 mm retention target, it is proposed to make use of infiltration within the rear-yard infiltration trenches wherever possible. Providing infiltration trenches and disconnected roof leaders directed towards lawn areas will provide lot level mitigation. To further maximize infiltration each infiltration trench will provide additional sub-surface infiltration volume via the installation of a linear gravel bed parallel to the length of rear-yard swales, allowing for

flows to first percolate into underlying gravel storage and infiltrate prior to running off to the storm sewer. This strategy will mitigate the overall runoff volume which will drain to the downstream SWM tanks during smaller storm events.

**Table 2-9: Summary of Site Retention Requirements**

| Area ID  | Area (ha) | Imp. (%) | Required 5mm Retention Volume (m <sup>3</sup> )* | Provided Infiltration Trench Vol. (m <sup>3</sup> ) | Provided Bioretention Cell Vol. (m <sup>3</sup> ) | Total Provided Retention Volume (m <sup>3</sup> ) |
|----------|-----------|----------|--------------------------------------------------|-----------------------------------------------------|---------------------------------------------------|---------------------------------------------------|
| 01 + 101 | 29.61     | 60%      | 890                                              | 533                                                 | 409                                               | 942                                               |
| 02 + 201 | 22.89     | 60%      | 690                                              | 378                                                 | 347                                               | 725                                               |
| Total    | 52.50     | 60%      | <b>1,580</b>                                     | 911                                                 | 756                                               | <b>1667</b>                                       |

\*Volume = Area(ha) x IMP (%) x 10 x 5mm

\*\*Area includes New Well area of approximately 0.20 ha

However, due to the configuration of the site, not all lots can provide lot level retention measures. As such, end-of-pipe infiltration is also proposed, which will be provided via centralized bioretention features strategically placed downstream of each SWM Tank's outlet. This will ensure that all flows to these bioretention cells are first treated via the proposed SWM Pond Wet Cells.

Preliminary sizing calculations for each LID feature are provided in Appendix B for reference. The final LID sizes will be confirmed and updated at the detailed design stage. The preliminary location and size of the above LID's are depicted in Figure 2-3, and are shown in the Functional Engineering drawings provided in Appendix E.

## 2.7.2 Water Balance and Groundwater Recharge

The subject site was reviewed using the Ontario Source Protection Information Atlas. Based on the results of this search, the site is not within any current wellhead protection area. However, it was acknowledged that the site is situated within a Significant Groundwater Recharge Area (SGWRA), as well as an area tributary to a highly vulnerable aquifer. Furthermore, a future Town Drinking water well is to be located adjacent to the site and will therefore place the site within a future well head protection area (WHPA).

In order to quantify the impact of the proposed development on site water balance, a Pre- and Post-Development Water Balance assessment was conducted by Soil Engineers Ltd, dated March 2023. Relevant excerpts from this analysis are provided in Appendix B. Based on Soil

Engineers Ltd.'s assessment it is expected that the site's annual pre-development infiltration rate is 128,332.98 m<sup>3</sup>/year. As a result of the proposed development, additional impervious areas are expected to reduce the site's infiltration rate and increase site runoff. Soil Engineers' assessment of the post-development condition anticipates a post-development infiltration rate of 67,407.44 m<sup>3</sup>/year, which translates to an expected 60,925.54 m<sup>3</sup>/year post-development infiltration rate deficit once the site is developed.

As indicated by Soil Engineer's Hydrogeological Assessment, dated March 2023, the site soils consist of sandy loam and are generally in favour of infiltration. In order to mitigate the above deficit, a series of LID's have been proposed including infiltration trenches and bioretention cells in order to achieve the 5mm erosion criteria through infiltration.

Using the proposed Bioretention Cells and Infiltration Trenches as mitigation measures, it is anticipated that the site can provide an infiltrate volume of approximately 1,667 m<sup>3</sup>, equivalent to the infiltration of the first 5.29mm of rainfall on site (i.e.  $1,667 \text{ m}^3 \div [52.5 \text{ ha} \times 60\% \text{ IMP} \times 10] = 5.29 \text{ mm}$ ). With these measures it is anticipated that a significant amount of groundwater recharge will be provided by utilizing the aforementioned centralized and de-centralized LIDs.

It is further noted that if additional infiltration is found to be required, other LID options can also be employed. A full list of all measures which are suitable to meet on-site water balance include:

- **Back-yard Infiltration Trenches** - promote infiltration of roof water;
- **Bioretention Cells/Facilities** – promote infiltration at the site stormwater outlet as an end-of-pipe infiltration method;
- **Bio-swales, Enhanced Grass Swales, and Rain Gardens** – promote infiltration of runoff from roadways from landscape boulevards;
- **Clean-water-collector system** – perforated infiltration system to infiltrate clean roof water across the site;
- **Roof Top Disconnection** – promote infiltration/evapotranspiration of roof water within lawn areas;
- **Topsoil amendment** - to increase the abstraction of runoff within proposed sodded lawn areas.

It is anticipated that the above mitigation measures will enable the proposed development to obtain a post to pre-development water balance. A detailed assessment of the impact, sizing, and final selection of the proposed LID measures on the site water balance will be conducted at the detailed design stage when suitable locations and sizing's are confirmed.

Preliminary sizing's of the bioretention cell and infiltration trenches have been performed and have been designed such that a maximum drawdown time of 48-hours is achieved. These sizing calculations are provided in Appendix B for reference. The final infiltration volumes, LID sizing's and locations will be refined and confirmed at the detailed design stage.

It is lastly noted that no LID measures are proposed to be located within 100-meters of the future Town drinking water well (see extent on Figure 2-3) as per SWG policy 11.

### 2.7.3 Wetland Assessment

As identified by the CVCA, a wetland is present within the Block 437 Woodlot. As per the CVCA's design criteria, the amount of flow draining towards the existing wetland should be maintained to ensure the future viability of the wetland.

In order to mitigate the potential for increased flows to the existing wetland, a series of design approaches have been considered for implementation in the final site design. Each solution aims to increase runoff travel times or reduce developed drainage area to the wetland in an effort to reduce flows. These mitigation measures include:

- Rooftop Redirection – Roofs from lots adjacent to Block 437 will be directed towards the front of the house (i.e. towards the right of way), minimizing the increase in drainage area to the wetland;
- Downspout Disconnections – Where roof drainage cannot be directed to the front, downspouts can drain towards backyard lawns, increasing the travel time of roof runoff over pervious surfaces;
- Rear-yard Swales – Implementation of rear-yard swales or level spreaders run along the back of lots to encourage infiltration of lot level flows. This will also increase travel times for flows as runoff during small storm events will first fill the swale and percolate into the ground, before larger flows run off the properties.

It should also be noted that the use of rear-lot catchbasins was also considered, as an effective way to reduce the contributing area draining towards the wetland, by conveying runoff flows towards the site's minor system. However as per the Town's request, the use of rear-lot catchbasins is to be minimized due to maintenance concerns within private properties. If this position should change, rear-lot catchbasins can be implemented as an additional mitigation method.

A detailed quantification of flows in the pre- and post-development condition towards the existing

wetland, will be conducted at the detailed design stage to ensure the aforementioned mitigation measures are effective.

## 2.8 Outlet Capacity

As mentioned in previous sections, the site's quantity control design will consist of two (2) SWM Ponds, which will regulate flows to the two existing site outlets. These outlets include:

1. The North Outlet : A 1.0 m by 1.8 m CSP culvert crossing beneath Trafalgar Road, from the subject site to an outlet located within a ditch along the south boulevard of Station Street; and
2. The South Outlet : A 600 mm diameter CSP culvert, crossing the Elora Cataract Trailway, to the existing Trafalgar Road minor storm sewer system, consisting of a 250 mm to 450 mm diameter storm sewer, draining to a headwall adjacent to Jane Street.

In order to ensure the existing outlets, have sufficient capacity to safely convey flows from the proposed development to the downstream watercourse, an analysis of the downstream storm infrastructure capacity was conducted. Flow master was used to estimate the capacity of both downstream culverts. The analysis results are summarized in Table 2-10.

Lastly, it should be noted that the flow controls proposed within each SWM Pond are to maintain post-development flow rates to pre-development levels at each of the above-mentioned outlets. Table 2-10 shows and compares the outlet capacity to the maximum pre-development flow rate estimated to drain to each outlet. Detailed capacity calculations are provided in Appendix B.

**Table 2-10: Summary of Outlet Capacities**

| Outlet | Dimension   | Classification | Full Flow Capacity (m <sup>3</sup> /s) | Required Capacity for Post to Pre-Flow Matching (m <sup>3</sup> /s) |
|--------|-------------|----------------|----------------------------------------|---------------------------------------------------------------------|
| North  | 1.0 x 1.8 m | CSP Culvert    | 4.35                                   | 4.91                                                                |
| South  | 600 mm dia. | CSP Culvert    | 0.46                                   | 2.04                                                                |

Based on the estimated capacities of each outlet, capacity constraints are anticipated within the existing downstream stormwater conveyance system. In order to alleviate this issue, two solutions are recommended. These include:

1. Overcontrolling the release rates from Pond 1 (North) to within the maximum capacity of the existing 1.0 x 1.8 m culvert for storm events which are anticipated to exceed the existing capacity. This solution is described and accounted for in Section 2.3.2.

2. Upgrading of the existing 600 mm culvert to convey the greatest pre-development flow control level from Pond 2 (South).

Furthermore, it should be noted that the existing sewers along Trafalgar Road, downstream of the existing 600 mm culvert, range from 250 mm diameter up to 525 mm diameter at the existing sewer outfall. As these sewers are smaller than 600 mm diameter, it is anticipated that sewer upgrades will be required from the Pond 2 outlet up to the existing sewer outfall to ensure that the downstream municipal sewer system has capacity to convey flows from Pond 2 up to the existing watercourse.

This solution is recommended in favour of overcontrolling Pond 2 outflows. Based on the pre-development flow estimates the existing system currently does not have capacity to convey flows even in the existing site conditions. As such upgrading of the storm sewer capacities in this location is anticipated to alleviate an existing capacity constraint in this area.

The final design solution to be used to alleviate capacity constraints will be confirmed in consultation with the Town, to ensure a preferable solution is reached. Design of any and all associated storm sewer upgrades which are required will be provided at the detailed design stage once a preferred solution is agreed upon with the Town.

## 2.9 Proposed Major and Minor System Capacity

In addition to meeting the site's quantity control criteria, it is critical that the proposed development also provide sufficient conveyance capacity within the proposed major and minor drainage system to safely convey runoff to the proposed SWM facilities. As per the Town of Erin's municipal design criteria the major and minor system should provide sufficient capacity to ensure that ponding from runoff be limited along the proposed right of ways such that private properties are protected from flooding. Furthermore, when conducting such checks, the largest flow of the 100-year and Regional Storm Event should be considered.

As part of the hydrological analysis conducted using VO (described in Section 2.3.2) the incoming 100-year runoff and Regional Storm flows rates to each of the two (2) proposed SWM Ponds was estimated. These flows are presented in the following table.

**Table 2-11: Summary of Site Retention Requirements**

| Storm Distribution        | Flows to Pond 1 (North)<br>(Catchments 01 + 10) | Flows to Pond 2 (South)<br>(Catchments 02 + 20) |
|---------------------------|-------------------------------------------------|-------------------------------------------------|
|                           | Flow (m <sup>3</sup> /s)                        | Flow (m <sup>3</sup> /s)                        |
| 100-yr 4hour Chicago      | 13.360                                          | 10.684                                          |
| 100-year 48hour Bloor SCS | 8.909                                           | 6.340                                           |
| Regional Event            | 7.993                                           | 3.714                                           |

Based on the above flow estimates, the most critical storm event was found to be the 100-year 4-hour Chicago Storm event, which had the highest flow rate. As a result, the proposed major and minor conveyance systems shall be sized to convey the flow from the 100-year 4-hour Chicago event. A detailed dual-drainage hydraulic model (such as an OTTSWM model) will be performed at the detailed design stage to confirm that the size of the minor sewer system's pipes and major overland conveyance route is adequate to safely convey flows to the proposed SWM facilities.

In addition to the major and minor conveyance systems, each SWM Pond will be equipped with an emergency spillway which will release excess flows to Trafalgar Road in the case that the pond's outlet clogging or a storm event in excess of the 100-year return period. At the detailed design stage each SWM Pond's emergency spillway will be sized for the most critical storm event peak flows as described above. Preliminary VO modeling output is provided in Appendix B.

## 3.0 Sanitary Servicing

### 3.1 Existing Sanitary Sewers

Town records were used to identify any existing Town wastewater infrastructure in the area. Based on these records, no existing sanitary infrastructure was found to be located in proximity to the site.

In order to provide adequate servicing of future sanitary demands in this area, and for the proposed development, WSP is currently working on the design of a sanitary trunk sewer on behalf of the Town of Erin. At the time of writing, it is understood that WSP's preliminary design proposes the new sanitary trunk sewer will be directed southwards along Trafalgar Road and will change alignment to follow the Elora Cataract Trailway at the trail's intersection with Trafalgar Road. From here flows will be directed to a new wastewater treatment facility, located away from the proposed development. The future sanitary sewer system is depicted in Figure 3-1, as well as on the engineering drawings in Appendix E.

### 3.2 Design Criteria

The sanitary flow calculations are based on the following Town of Erin sanitary sewer design criteria:

- Domestic sewage flow rate for residential area is 290 L/cap/day.
- Infiltration rate is 0.29 L/s/ha of gross area.
- Harmon Peaking Factor, M is  $1 + 14/(4 + P^{0.5})$ , where P is population in thousands, where the maximum value of M is 4.0, and minimum is 2.0. The peaking factor for commercial areas is 1.0.
- Sewer flow velocities at full flow should be restricted to:
  - Minimum velocity of 0.6 m/s
  - Maximum velocity of 3.0 m/s
- Pipe capacity calculations should be based on the Manning's formula, where roughness coefficient of  $n = 0.013$  for concrete and PVC pipes.
- Minimum pipe diameter shall be 150 mm for industrial, commercial or pipes servicing multiple residential services.

In addition to the standards set out by the Town of Erin's design criteria for sanitary services,

it is also known that a portion of the site will be located in a future Well Head Protection Area (WHPA). In accordance with comments received from Wellington Source Water Protection staff, a WHPA-A will be designated in the future, corresponding with the location of the new drinking water well at the northeast limit of the development.

In accordance with Policy SWG-13 for WHPA-A's, all sanitary sewers which are located within a 100-meter radius of the future well (see Figure 3-1) shall follow higher construction standards and inspection protocols by the owner in order to minimize and eliminate leaks. The specific standards to be applied in this development will be confirmed with the Issuing Director of Environmental Compliance Approval for these sewers at a later stage of the project.

### 3.3 Proposed Sanitary Servicing

The proposed sanitary servicing layout includes a system of internal sanitary sewers which will be designed to drain via gravity from the north property boundary towards the south. In order to better service the site, and prevent excessively deep sewers, the subject site is proposed to be split into two (2) sanitary catchment areas, each serviced by separate outlets. These outlets will drain to the future Trafalgar Road sanitary trunk sewer and will flow southwards to the future wastewater treatment plant (WWTP). The site's sanitary outlets will be located at the two primary site access points located at the current termination of Station Street and Market Street respectively.

At the time of writing WSP's design of the sanitary trunk sewer along Trafalgar Road is 450 mm diameter. Coordination and discussion with the Town and their design engineers will be held at future design stages to ensure that the future trunk sewer and WWTP design are compatible with the proposed development sewers.

The proposed development design populations have been estimated and presented in Section 1.4. The total site sanitary peak flow anticipated to be generated by this development is summarized in Table 3-1. Detailed sanitary demand calculations are provided in Appendix C.

**Table 3-1: Proposed Sanitary Flow Estimate**

| Land Use    | Area (ha) | Population | Average Flow (L/s) | Peak Factor | Peak Flow (L/s) | Infiltration Flows (L/s) | Total Sanitary Peak Flow (L/s) |
|-------------|-----------|------------|--------------------|-------------|-----------------|--------------------------|--------------------------------|
| Residential | 52.3      | 2976       | 9.99               | 3.45        | 34.42           | 13.59                    | 48.01                          |

It should also be noted that the proposed sewer design has considered future support for gravity

sewer connections from potential future development lands to the south. Similarly, on the north side of the site consideration has been provided for connection points from existing areas to the north along Currie Road and Spruce Street, should it be determined that these areas will also be serviced to the proposed development's sewers. The proposed sanitary sewer system is illustrated on Figure 3-1 as well as the Preliminary Engineering Drawings, provided in Appendix E.

### 3.4 Servicing Allocation

As mentioned, the Town is currently undergoing improvements to the Town's sanitary sewerage system capacity. At the time of writing, the property owner has entered into both an *Allocation Agreement* and *Front Ending Agreement* with regards to the sanitary capacity of the new Town Wastewater Treatment Plant. In exchange for these agreements, the Town has awarded an allocation of 700 Single-Detached Equivalents (SDE). The breakdown of the equivalent units in comparison to the proposed unit breakdown is shown in the table below.

**Table 3-2: Proposed Single-detached Equivalents (SDE)**

| Unit Type       | Proposed Unit Count | SDE Conversion Rate | Proposed SDE Units |
|-----------------|---------------------|---------------------|--------------------|
| Single-Detached | 376*                | 1.0                 | 376                |
| Townhouse       | 286                 | 0.72*               | 206                |
| Total           | 662                 | -                   | <b>582</b>         |

\*Conversion rate for "Multiples" dwellings to one (1) SDE.

Based on the table above, as per the current draft plan, the proposed development's equivalent unit counts, considering the current Single Detached Home and Townhouse unit counts, remain within the 700 single-detached equivalent (SDE) units allocated for the Town's future sanitary design capacity. Based on the above breakdown, adequate sanitary capacity to service the proposed Single-Detached homes and Townhouse blocks are expected to be provided by the Town's future wastewater treatment facilities.

Note that Capacity for the proposed seniors' residences (both low-rise and apartment) should be confirmed once unit counts are made available. A summary of the anticipated peak flow capacity associated with the 700 SDE units is provided in Table 3-3.

**Table 3-3: SDE Allocation Sanitary Demand**

| Land Use    | SDE Unit Count | Design Population (2.8 ppl/unit)* | Average Flow (L/s) | Peak Factor | Peak Flow (L/s) |
|-------------|----------------|-----------------------------------|--------------------|-------------|-----------------|
| Residential | 700            | 1960                              | 6.58               | 3.59        | <b>23.63</b>    |

\*As per the Town of Erin Engineering Design Guidelines.

\*\*Estimate does not include infiltration peak flows.

Lastly, it should be noted that the capacity required to adequately service the proposed seniors blocks 423 and 424 will be dependant on the proposed block design. At this time the final proposed block design is still to be determined. As a result, any additional allocation required for these blocks will be handled in the future by a separate site plan application for these blocks.

## **4.0 Water Supply Servicing**

### **4.1 Existing Water Supply Infrastructure**

Based on existing municipal records, homes north of the proposed development are currently within serviced by the original Village of Hillsburgh's water supply system. This system is serviced by the two existing municipal wells H2 and H3, north of the site, as indicated by the Town of Erin's Urban Centre Water Servicing Class EA (February 2020). Existing 150mm diameter watermains are present along Spruce Street, and Douglas Crescent, directly adjacent to the site's north boundary.

As per the Town of Erin's Urban Centre Water Servicing Class EA (February 2020), it is known that future expansions to the Town's water system are anticipated to be required to adequately service the township as further growth occurs. In particular relevance to the proposed development, the Class EA recommends the provision of a future water tower within the subject site area near the existing termination of Currie Drive. Furthermore, as per the Town's Pre-consultation response letter, dated March 30<sup>th</sup>, 2022, a sufficiently sized block should be provided within the subject development to provide an elevated water tower (storage reservoir) adjacent to the new water well block.

In addition, the Town has confirmed that a new watermain will be constructed along Trafalgar Road by the Town as part of the Town's sanitary servicing improvement project along this road. As such the site will be required to provide connections to the future watermain to be constructed along Trafalgar Road.

As a result of the above, the Town's construction of the future elevated water tower and future watermain along Trafalgar Road is expected to be necessary to ensure that adequate water service capacities are available on-site.

### **4.2 Design Criteria**

The following represents a brief summary of the Town of Erin's design criteria for water supply infrastructure.

Typical Water Demand Criteria:

- Average Daily Consumption Rate for Residential area is 290 L/cap/day
- Average Daily Consumption Rate for School area is 95 L/cap/day

- Average Daily Consumption Rate for Industrial area is 9 m<sup>3</sup>/ha/day
- Average Daily Consumption Rate for Commercial area is 28 m<sup>3</sup>/ha/day
- Minimum Day Demand Factor for Residential area is 0.40
- Maximum Day Demand Factor for Residential area is 2.75
- Maximum Hourly Demand Factor for Residential area is 4.13

Fire Flow Requirements:

- Minimum Allowable Flow Rate for Residential Area is 57 L/s at 138 kPa (20 psi), with a preferred rate of 76 L/s at 140 kPa (20 psi);
- Minimum Allowable Flow Rate for Institutional Area is 91 L/s at 138 kPa (20 psi) , with a preferred rate of 114 L/s at 140 kPa (20 psi);
- Minimum Allowable Flow Rate for Commercial / Industrial Area is 136 L/s at 138 kPa (20 psi), with a preferred rate of 152 L/s at 140 kPa (20 psi);

### 4.3 Proposed Water Supply Servicing

Water supply servicing for the subject site will be provided according to the Town of Erin design criteria. The proposed watermain system will be designed to provide water connections for each unit throughout the site. Looping will be provided internally for dead ends, as well as via multiple site connections to the existing Town water supply system in order to provide redundancy.

It is the intention of the proposed development to accommodate the recommendations of the Town of Erin's Urban Centre Water Servicing Class EA with the inclusion of a Future Water Tower (Block 440), as shown on the current draft plan (see Appendix A for reference). Watermain connections from the site to the existing Erin water supply system will be proposed via connections to existing watermains to the north by extending a watermain along future Street '2'. Connection points are proposed at both Currie Road and Spruce Street as well as to the future watermain to be constructed by the Town along Trafalgar Road. Watermains will be extended from the water tower block throughout the site to distribute water services to each of the development blocks and proposed residences.

In addition, two (2) outside connection points are proposed to facilitate a connection to the future watermain to be constructed by the Town along Trafalgar Road. These points will be located at the site's primary site access points, where Station Street, and Market Street currently terminate. This scheme will allow adequate water distribution across the development, while integrating the

future water tower with the larger Town of Erin water supply system.

It is also understood that the Town is currently in the process of completing a comprehensive water supply system model for the Town of Erin. The appropriate sizing of on-site watermains, future water towers, as well as the size of the existing Erin water supply network should be confirmed based on the final Town of Erin water supply model once it is completed. Therefore, details of the proposed water supply system, as well as potential outside improvements to existing infrastructure, will be confirmed at later design stages. When the Town model is available, a comprehensive analysis will be conducted at the detailed design stage to ensure that the existing and proposed water distribution system are sufficient to service the proposed development.

Furthermore, in order to ensure adequate servicing capacity is available for the proposed development, the construction timing of the subject development will be coordinated with the Town regarding the new municipal well, elevated water tower, and future watermain along Trafalgar Road, to ensure adequate measures are in place prior to completion of the project.

The estimated water supply demands for the proposed development are presented in Table 4-1. The minimum fire flow rate has been estimated based on the preferred residential fire flow rate, as indicated by the latest Town of Erin design guidelines. All detailed water supply calculations are provided in Appendix D, and the proposed water supply system is depicted schematically in Figure 4-1.

**Table 4-1: Estimated Residential Water Supply Demands**

| Land Use                | Expected Population <sup>(1,2)</sup> | Average Day Demand <sup>(3)</sup> (L/s) | Peak Hour Demand <sup>(4)</sup> (L/s) | Max. Day Demand <sup>(5)</sup> (L/s) | Fire Flow (L/s) | Max Day + Fire (L/s) |
|-------------------------|--------------------------------------|-----------------------------------------|---------------------------------------|--------------------------------------|-----------------|----------------------|
| Residential & Mixed-Use | 2976                                 | 9.99                                    | 41.25                                 | 2.75                                 | 76.00           | 104.47               |

Note:

- (1) Expected population based on population estimate in Section 1.4
- (2) Expected Mixed-Use Population included in population estimate.
- (3) Based on average day consumption rate as 290 l/cap/day
- (4) Based on peak hour factor as 4.13
- (5) Based on maximum day factor as 2.75

Lastly, stub connections to the proposed water distribution system have been provided along the southern and eastern property lines to facilitate connections to future developments.

## 5.0 Floodplain

As part of the design of the proposed development, CVCA regulatory and flood plain mapping was consulted. The subject development is located within the West Credit River basin, and as such the associated flood mapping was reviewed. As per CVC Flood Risk Mapping, the site is depicted on West Credit River Map 08 and 09. Using these maps, a flood plain spill point was identified, located at the northwest corner of the site.

The impact of this feature on the proposed development was investigated in a memorandum produced by Urbanworks Engineering Corporation, dated June 2023. A one-dimensional hydraulic analysis was conducted and was discussed in this memorandum. As per the findings of this analysis, the existing floodplain exhibits spill of flows from Spruce Street towards the site.

Under the proposed condition, a steady state HEC-RAS analysis showed that no spill occurs during the 100-year event, but during the Regional even a maximum estimated flow of  $5.05 \text{ m}^3/\text{s}$  is anticipated to spill onto the site. At the time of writing the memorandum estimated that the proposed subdivision's right-of-way would have sufficient capacity ( $15 \text{ m}^3/\text{s}$ ) to convey flows from the regional storm event, while having a flow depth of 0.10 m above the proposed gutter elevation. As such the regional flood limit was anticipated to sit safely within the proposed right-of-way along Street 2, and away from proposed homes.

However, due to the complexity of this flood plain spill point it is proposed to conduct a detailed two-dimensional analysis to assess the impact of this spill point on the proposed development. This analysis is being conducted by Urbanworks Engineering Corporation and will be completed and submitted at a later design stage under separate cover. The results of this analysis will be used to inform the final design of the development and any required changes to the design will be made at that stage.

## 6.0 Erosion & Sediment Control Measures

A preliminary Erosion and Sediment Control (ESC) Plan for the proposed development has been prepared in accordance with the December 2006 Erosion and Sediment Control Guidelines for Urban Construction (Greater Golden Horseshoe Conservation Authorities) and as per the current Town of Erin standards and requirements.

The proposed erosion and sediment control works during construction will consist of the following:

- temporary silt fences;
- sediment traps;
- two (2) sediment control ponds;
- sediment traps for the catchbasins and manholes;
- mud mats at the construction access point; and
- cut-off swales;
- two (2) topsoil stockpiles, equipped with silt fencing;

A functional Erosion and Sediment Control plan is provided in Appendix E which presents the above strategies. The final erosion and sediment control measures to be used, and their locations, on-site will be confirmed at the detailed design stage.

## 7.0 Utilities

In order to ensure the adequate servicing of the proposed development, a high-level investigation of other available infrastructure was conducted.

### 7.1 Existing Utilities

Based on existing site records, and those of adjacent roadways the following utilities were identified and available for future connections.

#### Hydro-Electric Distribution

- An above ground electric distribution line, by Hydro One, is located within the west boulevard of the Trafalgar Road right-of-way.

#### Gas

- A 100 mm diameter gas main, by Enbridge, is located along the east boulevard of the Trafalgar Road right-of-way.
- A 100 mm diameter gas main, by Enbridge, is located along Spruce Street.

#### Telecommunications

- Bell telecommunication lines along Trafalgar Road;
- Rogers telecommunication lines along Trafalgar Road;

The approximate locations of the existing utilities mentioned above are depicted on the preliminary servicing and grading plans provided in Appendix E. Utility providers and an authorized locates provider should be consulted when conducting any works on or nearby the above-mentioned infrastructure.

### 7.2 Future Considerations

As part of the considerations for the proposed development, each utilities provider (i.e., Hydro One, Enbridge, Rogers & Bell) will be consulted regarding extending services to the proposed subdivision. Any anticipated utilities upgrades needed to adequately service the proposed development shall be confirmed by their respective provider during the detailed design stage.

Furthermore, it is noted that at the time of writing, preliminary comments provided by Hydro One, Bell and Rogers, have suggested that there are no anticipated concerns with regards to the ability to provide adequate Hydro-Electrical or Telecommunications services for the proposed development. Design confirmation and coordination from each service provider regarding any required servicing upgrades required to service the site will be obtained during the detailed design stage.

## 8.0 SUMMARY

This report outlines the desired stormwater management and servicing scheme for the proposed residential Hillsburgh Subdivision development east of Trafalgar Road, North of Wellington Road 22, in the Town of Erin. The following summarizes the conclusions and recommendations of this report:

### Stormwater Management

- Post to pre-development peak flow matching is proposed to meet site quantity control criteria;
- Detention storage is required on site and will be provided using two (2) conventional SWM Pond facilities. Flows draining from the SWM ponds will be regulated to within the site's quantity control requirements;
- Retention of 5 mm of rainfall for erosion control and water balance mitigation is proposed to be achieved through infiltration trenches and centralized bioretention cells.
- Quality control will be provided using two (2) end-of-pipe Wet Cells within the proposed SWM Pond facilities. Each wet cell has been sized according to the MOE 2003 criteria to provide an enhanced level of protection (80% TSS removal) for each of their incoming drainage areas.
- A site water balance assessment was conducted by Soil Engineers Ltd. Infiltration trenches, bioretention, rooftop lead disconnection and topsoil amendment are proposed as options to mitigate site water balance. A detailed mitigation water balance will be provided at the detailed design stage.

### Sanitary Servicing

- Site sanitary flows are proposed to drain in a south westerly direction via a proposed internal sanitary sewer network.
- A future sanitary trunk sewer is currently planned to be constructed along Trafalgar Road and the Elora Cataract Trailway and is being designed by WSP on behalf of the Town. The site will be serviced to the future sanitary trunk sewer with two outlet locations at Station Street and Market Street.
- The Sanitary capacity of the Trafalgar Sanitary trunk sewer will be confirmed and coordinated with the Town's wastewater treatment plant design during the detailed

design stage to ensure compatibility with the proposed development.

#### Water Supply Servicing

- An internal water supply network will be directly fed by a future proposed water tower and new well block on the site's northern boundary;
- Sizes of the future water tower will be established and designed by the Town as per the results of their upcoming Town water supply model. Pipe sizes to accommodate the water tower will be coordinated at the detailed design stage.
- Connection points from the site to the Town's water supply network will be provided to the future Town watermain extension along Trafalgar Road to the East, as well as to existing watermains to the north.
- Additional water distribution system stubs have been provided along the south and east property lines to facilitate connections to potential future developments.

#### Utilities

- Existing Gas, Telecommunication and Hydroelectric services are present along Trafalgar Road. Any required upgrades will be confirmed with service providers at the detailed design stage.

## 5.0 **SOIL LITHOLOGY**

The investigation has revealed that beneath the topsoil and ploughed soil horizons at the ground surface, the subject site is underlain, predominantly by sand and gravelly sand deposits. Sandy silt to silty sand till or silt deposits were generally contacted within the lower stratigraphy in some of the boreholes. A localized sandy silt deposit was also contacted near the ground surface, below the ploughed soil layer in Borehole 6.

### 5.1 **Topsoil/Ploughed Soil** (All BH/MWs)

The thickness of the revealed topsoil horizon is approximately 36 cm where it extends to depths of 0.5 to 0.9 mbgs. The ploughed soil layer consists of dark brown sand with occasionally rootlets inclusions. The moisture contents for the retrieved subsoil samples ranges from 13.6 to 19.3%. High moisture contents are attributed to the topsoil and its organic inclusions.

### 5.2 **Sand** (All BH/MWs except BH/MWs 4, 6 and 8)

Sand was contacted below the ploughed soil layer within all the boreholes, except BH/MWs 4, 6 and 8. It extends to depths, ranging from 1.0 to 6.6 mbgs. Its relative density varies from very loose to very dense, being generally compact. It is mostly fine to medium grained with occasional gravel inclusions. The moisture contents for the retrieved subsoil samples ranges from 4.2 to 11.4%, indicating moist to very moist conditions. Its colour remains brown. Grain size analysis on one subsoil sample from BH/MW 7 at a depth of 4.8 mbgs indicates the estimated permeability is about  $10^{-3}$  m/sec, with the soil gradation being plotted on Figure 12.

### 5.3 **Gravelly Sand/Sandy Gravel** (All BH/MWs except BH/MWs 7 and 11)

Gravelly sand/sandy gravel deposits were encountered in the lower soil stratigraphy, below the sand or sandy silt layer. The relative density for the gravelly varies from compact to very dense. The soil colour remains brown and includes occasionally cobbles and boulders. The moisture contents for the retrieved subsoil samples ranges from 2.6 to 12.4%, indicating damp to saturated conditions. The saturated samples were found at lower depths, generally about 5 mbgs. Grain size analysis on one subsoil sample from BH/MW 1 at a depth of 3.3 mbgs indicates the estimated permeability is about  $10^{-3}$  m/sec with the subsoil sample gradation being plotted on Figure 13.

Reference No. 2206-W054

5.4 **Silty Sand Till and Sandy Silt Till** (BH/MWs 1 and 5)

Silty sand till and sandy silt till deposits were contacted locally at the bottoms of BH/MWs 1 and 5 below gravelly sand deposit. The relative density varies from dense to very dense. They contain traces of gravel and clay, become gravelly in places with occasionally cobbles and boulders. The silty sand till becomes grey at a depth of 4.5 mbgs in BH/MW 1. Grain size analysis on four subsoil samples indicates the estimated permeability ranges from  $10^{-4}$  m/sec to  $10^{-5}$  m/sec with the subsoil sample gradation being plotted on Figures 14 to 16.

5.5 **Sandy Silt/Silt** (BH/MWs 6, 8 and 11)

A layer of sandy silt was encountered within the upper zone of BH/MW 6, where it extends to a depth of 2.2 m. The silt deposit was found at the bottom of BH/MWs 8 and 11. The sandy silt is compact and moist, and remains brown. The silt is dense to very dense and becomes grey at a depth of 6.4 mbgs within BH/MW 11.

## 6.0 **GROUNDWATER STUDY**

### 6.1 **Review Summary of Concurrent Report**

A review of the findings from the concurrent geotechnical soil investigation report (SEL Reference No. 2206-S054) has disclosed that beneath a layer of topsoil/ploughed soil horizons, the subject site is underlain, predominantly by sand and gravelly sand deposits. Sandy silt to silty sand till, or silt was contacted within the lower stratigraphy within some of the boreholes. A local sandy silt deposit was also encountered near the ground surface, below the ploughed soil horizon in BH/MW 6.

### 6.2 **Review of Ontario Water Well Records**

The Ministry of the Environment, Conservation and Parks (MECP) water well records for the subject site, and for the properties within a 500 m radius of the boundaries of the subject site (study area) were reviewed.

The records indicate that one hundred and forty (140) well records are located within the study area relative to the subject site boundaries. The locations of these well records, based on the UTM coordinates provided by the records, are shown on Drawing No. 3. Details for the MECP water well records that were reviewed are provided in Appendix A.

A review of the final status and of the well records within the study area reveals that ninety-six (96) are registered as water supply wells, two (2) are registered as test hole wells, one (1) well is registered as having other status, ten (10) are registered as observation wells, three (3) are registered as monitoring and test hole wells, two (2) are registered as abandoned-supply wells, twenty-one (21) are registered as abandoned-other wells, and five (5) wells are registered as having unknown statuses.

A review of the first use of the well records reveals that five (5) are registered as test hole wells, seven (7) are registered as public supply wells, six (6) wells are registered as not being used, one (1) is registered as a municipal well, eight (8) are registered as monitoring wells, one (1) is registered as a livestock well, eighty-two (82) are registered as domestic wells, two (2) are registered as commercial wells, and twenty-eight (28) wells are registered as having unknown statuses.

Should there be any water supply wells discovered during the future site grading operations, we recommend that they be properly decommissioned in accordance with the Ontario Water resources Act, Regulation 903.

### 6.3 Groundwater Monitoring

The groundwater levels in the monitoring wells were measured, manually on December 1, 2022, January 5 and February 8, 2023, to record the fluctuation of the shallow groundwater table beneath the site. The recorded groundwater levels and their corresponding elevations are given in Table 6-1.

**Table 6-1 - Groundwater Level Measurements**

| Well ID  |      | December 1, 2022 | January 5, 2023 | February 8, 2023 | Fluctuation (m) |
|----------|------|------------------|-----------------|------------------|-----------------|
| BH/MW 1  | mbgs | 3.91             | 5.47            | 5.84             | 1.9             |
|          | masl | 435.72           | 434.16          | 433.79           |                 |
| BH/MW 2  | mbgs | DRY              | DRY             | DRY              | -               |
|          | masl | <430.06          | <430.06         | <430.06          |                 |
| BH/MW 3  | mbgs | 5.88             | 5.84            | 5.85             | 0.04            |
|          | masl | 428.17           | 428.21          | 428.20           |                 |
| BH/MW 4  | mbgs | DRY              | 3.88            | 3.90             | 2.20            |
|          | masl | <421.51          | 423.73          | 423.71           |                 |
| BH/MW 5  | mbgs | 4.94             | 4.90            | 4.80             | 0.14            |

| BH/MW 9  | mbgs | DRY              | DRY             | 4.35             | 0.05            |
|          | masl | <433.31          | <433.31         | 433.36           |                 |
| BH/MW 10 | mbgs | 5.83             | DRY             | DRY              | 0.27            |
|          | masl | 432.09           | <431.82         | <431.82          |                 |
| BH/MW 11 | mbgs | 3.85             | 3.88            | 3.68             | 0.20            |
|          | masl | 431.64           | 431.61          | 431.81           |                 |

*Notes*      *mbgs -- metres below ground surface*

*masl -- metres above sea level*

As shown above, the groundwater table levels are generally consistent with minor fluctuation. The groundwater level at BH/MW 2 was consistently below the bottom of the well, in which the well was interpreted as being dry, throughout the monitoring period. BH/MWs 4, 7 and 8 exhibited an increasing trend over the monitoring period. BH/MWs 1 and 10 exhibited a decreasing trend over the monitoring period.

Reference No. 2206-W054

groundwater level elevation of 428.6 masl at BH/MW 8 indicated that the lowest proposed excavation elevation is about 1.2 m above the groundwater table elevation. As such, it is not anticipated that construction dewatering for groundwater control will be required for the proposed SWM Detention Tank.

It is recommended to record the stabilized groundwater levels again over the spring season, from March to June, when groundwater levels are typically at their highest.

## **7.2 Groundwater Control Methodology**

Groundwater seepage rates into open excavations below the groundwater table may be controllable by occasional pumping from sump pits when and where needed during earthworks. However due to the unstable nature of sand and gravelly sand below the water table, the shallow groundwater table should be lowered in advance of excavations, if required. The final designs for the dewatering system will be the responsibility of the construction contractors.

Tables 7-1, which follows, summarizes dewatering flow estimates for the proposed residential structures and for the proposed the SWM area.

Reference No. 2206-W054

more detailed discussion for the groundwater function for the subject site will be provided in the final report once the monitoring program is completed.

#### 7.4 **Low Impact Development**

The surficial shallow soil beneath the subject site consists, predominantly of sand and gravel. Opportunities may exist to infiltrate collected runoff to the subsurface at the developed subject site, using appropriate Low Impact Development Infrastructure, which might include infiltration galleries or underground storage/exfiltration tanks.

LID infrastructure can be implemented in areas where the shallow groundwater is deeper than 1.0 m below the ground surface and where it is possible to maintain a minimum of 1.0 m separation between the bases of any proposed LID stormwater management infiltration infrastructure and the high groundwater table.

## 8.0 **CONCLUSIONS**

1. The site lies within the Physiographic Region of Southern Ontario known as the Hillsburgh Sandhills and is within a former spillway.
2. Based on review of the surface geological map of Ontario, the subject site is underlain by the Glaciofluvial ice-contact deposits at the northwest portion and the Glaciofluvial outwash deposits within the southeast portion. The Glaciofluvial ice-contact deposits consist of gravel and sand, includes esker, kame, end moraine, ice-marginal delta and subaqueous fan deposits. The Glaciofluvial outwash deposits consist of gravel and sand, includes also proglacial river and deltaic deposits.
3. The subject site is located within the Credit River Watershed.
4. A review of the topography map for the area, and from review of the ground surface elevations at the borehole and monitoring well locations, indicates that the subject site is generally descending towards the southwest, towards Trafalgar Road.
5. The findings from the current study reveal that beneath the topsoil and ploughed soil horizons, beneath the ground surface, the subject site is underlain, predominantly by sand and gravelly sand deposits. Sandy silt to silty sand till or silt deposits were generally contacted in the lower stratigraphy in some of the boreholes. A localized sandy silt deposit was contacted near the ground surface below the ploughed soil in Borehole 6.
6. The findings of this study confirm that the groundwater table level elevations range from <421.51 to 440.74 masl, The measured groundwater levels at the BH/MWs indicate that shallow groundwater is interpreted to be flowing in southwesterly directions, away from interpreted, localized groundwater high areas, located beneath the northwestern and eastern portions of the subject site. Shallow groundwater is interpreted to flow in the direction of the tributary for Credit River that is located southwest of the subject site.
7. The monitoring wells with sufficient groundwater volumes within them underwent single well response tests (SWRTs) to estimate the hydraulic conductivity at the depths for the monitoring well screens. The results for the SWRT's will be presented in the final hydrogeological assessment report. The single well response tests yielded hydraulic conductivity (K estimate) for the underlying sub-soils for gravelly sand/sandy gravel unit ranges from  $5.2 \times 10^{-7}$  to  $5.7 \times 10^{-7}$  m/s, and the K estimate for the silt and sand unit is  $3.6 \times 10^{-6}$  m/s. The results of the SWRT provide an indication of the yield capacity for the groundwater-bearing subsoil strata at the depths of the monitoring well screens. The above results suggest that the K estimate for the groundwater-bearing subsoils at the depths of the well screen is low to moderate with corresponding low to moderate anticipated groundwater seepage rates

Reference No. 2206-W054

- into open excavations, below the groundwater table.
8. Hazen Equation calculated permeability results indicate that the the K estimate for the sub-soil units beneath the subject site ranges from  $5.63 \times 10^{-5}$  to  $1.22 \times 10^{-5}$  m/sec. The results of the SWRT provide an indication of the yield capacity for the groundwater-bearing subsoil strata primarily above the depths of the monitoring wells screens. The above result suggests that the K estimate for the groundwater-bearing subsoils ranges from low to high with corresponding moderate anticipated groundwater seepage rates into open excavations, below the groundwater table.
  9. The measured groundwater levels at the BH/MWs indicate that shallow groundwater is interpreted to be flowing in southwesterly directions, away from interpreted, localized groundwater high areas, located beneath the northwestern and eastern portions of the subject site. Shallow groundwater is interpreted to flow in the direction of the tributary for Credit River that is located southwest of the subject site.
  10. The groundwater at the subject site is approximately 0.14 to 2.67 m below the base elevation for the proposed basement structures for portions of the residential housing buildings. It is therefore not anticipated that any construction dewatering will be required for earthworks and construction of the proposed houses.
  11. The groundwater levels in the vicinity of Block 508, where the stormwater management detention tank is located is approximately 0.5 m below the estimated proposed bottom levels, and, as such, it is not anticipated that dewatering for groundwater control will be required for the construction of this stormwater management, within this area of the proposed development.
  12. The dewatering flow estimates for construction of the proposed stormwater management detention tank located within the vicinity of Block 506 of the site, suggests that it could reach an estimated daily rate of 20,504.3 L/day; by applying a safety factor of three (3), it could reach a maximum of 61,512.8 L/day. This dewatering flow rate for excavation, is below the PTTW threshold limit of 400,000 L/day but is above 50,000 L/day threshold limit for requiring an approval, with the approval for the proposed groundwater takings for construction being required to be registered through an Environmental Activity and Sector Registry (EASR) with the EASR filing through the MECP.
  13. The highest estimated temporary dewatering flow rates for installation of the underground services could reach a maximum daily rate of 131,806.1 L/day; by considering a 3x safety factor, it could reach an approximate daily maximum of 395,418.3 L/day. Since the estimated dewatering flow rate exceeds 50,000 L/day but is below the 400,000 L/day PTTW threshold limit, the approval for any proposed temporary groundwater-taking for construction is by means of applying for an EASR approval with the MECP.
  14. The estimated zone of influence for any conceptual dewatering wells or dewatering array around excavation footprints could reach maximums of 47.0 m away from the

Reference No. 2206-W054

conceptual dewatering array around the servicing trenches.

15. The surficial shallow soil beneath the subject site consists, predominantly of sand and gravel. Opportunities may exist to infiltrate collected runoff to the subsurface at the developed subject site, using appropriate Low Impact Development Infrastructure, which could include infiltration galleries or underground storage/exfiltration tanks. LID infrastructure can be implemented in areas where the shallow groundwater is deeper than 1.0 m below the ground surface and where it is possible to maintain a minimum of 1.0 m separation between the bases of any proposed LID stormwater management infiltration infrastructure and the high groundwater table.

| Drawdown time (Dt)                | 47.8     | hours          | Total Drawdown = Drawdown Time (Ponding) + Drawdown Time (Gravel Bed)                                                                                                         |
| Total Volume Provided             | 409.4    | m <sup>3</sup> | Total Volume = (Provided Volume) x (Number of LIDs)                                                                                                                           |

\* As indicated by Soil Engineer's Preliminary Geotechnical Assessment for the site, Sand / Gravely Sand was found for the first 5.5 m at Boreholes 3 and 8. Sands/Gravel Sands typically exhibit infiltration rates in the range of 50mm/hr. This should be confirmed with in-situ testing at the detailed design stage by the site Soil's Engineer at the location of the proposed LID.

|-----------------------------|----------|----------------|--------------------------------------------------------------------------------------------|
| Infiltration Volume         | 458      | m <sup>3</sup> | Minimum infiltration volum required to provide 60% TSS removal (MOE 2003)                  |
| Number of LID's             | 1        |                |                                                                                            |
| Infiltration Volume Per LID | 458      | m <sup>3</sup> |                                                                                            |
| Max. Drawdown time          | 48       | hours          | (*Minimum Infiltration Rate assumed for Gravelly Sand, to be confirmed by In-situ testing) |
| Infiltration rate           | 45.00    | mm/h           |                                                                                            |
| Safety Factor               | 2.50     |                |                                                                                            |
| Design Infiltration Rate    | 18.00    | mm/h           |                                                                                            |
|                             |          |                | MOE 2003 Criteria - Equation 4.3                                                           |

## Proposed Infiltration

| Parameter                          | Quantity | Unit           | Comments                                                              |
|------------------------------------|----------|----------------|-----------------------------------------------------------------------|
| Provided Footprint Area            | 456      | m <sup>2</sup> | Maximum Depth of Ponding as recommended by MOE 2003, Section 4.6.6    |
| Surface Ponding Depth              | 0.60     | m              |                                                                       |
| Drawdown time of Ponding (Dtp)     | 33.3     | hours          |                                                                       |
| Ponding Volume                     | 274      | m <sup>3</sup> | Volume = (Area) x (Surface Ponding Depth)                             |
| Gravel Bed Depth                   | 0.40     | m              | Dtg = (Gravel Depth x Porosity) / (Design Infil. Rate / 1000)         |
| Stone Porosity                     | 0.40     |                |                                                                       |
| Drawdown time of Gravel Bed (Dtg)  | 8.9      | hours          |                                                                       |
| Provided Volume                    | 73.0     | m <sup>3</sup> | Volume = (Area) x (Depth) x (Porosity)                                |
| Drawdown time (Dt)                 | 42.2     | hours          | Total Drawdown = Drawdown Time (Ponding) + Drawdown Time (Gravel Bed) |
| Total Infiltration Volume Provided | 346.6    | m <sup>3</sup> | Total Volume = (Provided Volume) x (Number of LIDs)                   |

\* As indicated by Soil Engineer's Preliminary Geotechnical Assessment for the site, Sand / Gravelly Sand was found for the first 6.4 m at Borehole 10. Sands/Gravel Sands typically exhibit infiltration rates in the range of 50mm/hr. This should be confirmed with in-situ testing at the detailed design stage by the site Soil's Engineer at the location of the proposed LID.

**Re: Pre- and Post-Development Water Balance Assessment  
Proposed Residential Development  
63 and 63A Trafalgar Road  
Town of Erin**

Dear Madam:

We have completed a pre- and post-development water balance assessment for a proposed residential development, at the captioned site in the Town of Erin, and our findings are presented in this Letter Report.

- **Introduction**

The proposed development site is located at 63 and 63A Trafalgar Road in the Town of Erin. Drawing No. 1, enclosed, shows the location of the subject site for which this water balance applies. The proposed development will involve construction of residential development consisting detached dwellings, townhouses, having basement structures, along with mixed-used senior housing, parks and stormwater management pond blocks. The proposed development footprint encompasses an area of approximately 523,350 square meters.

- **Background**

Soil Engineers Ltd. (SEL) previously completed a preliminary geotechnical soil assessment, for the subject site, dated February 3, 2023 (SEL Reference No. 2206-S054). The study revealed that beneath a veneer of topsoil and ploughed soil, the site is underlain by strata of sand and gravelly sand deposits. Sandy silt till and silt deposits were generally contacted within the lower stratigraphy in some boreholes.

Soil Engineers Ltd. (SEL) also completed a hydrogeological assessment for the site in February 2023 (SEL Reference No. 2206-W054). This study reveals that the measured groundwater level elevations ranged from 440.74 to <421.51 masl, or from the depths, ranging from 2.75 to <6.2 mbgs as recorded during the monitoring period encompassing the period from December 1, 2022 to February 8, 2023. From the recorded groundwater level measurements, the shallow groundwater flow pattern was interpreted to flow in southwesterly direction, towards the tributary of Credit River.

The results of the completed hydrogeological assessment, indicates that the estimated permeability for the gravelly sand is  $5.2 \times 10^{-7}$ , the K estimate for the sandy gravel is  $5.7 \times 10^{-7}$  m/sec, the K estimate for the silt and sand till is  $3.6 \times 10^{-6}$  m/sec and the K estimate for the silty sand is  $2.10 \times 10^{-6}$  m/sec. This confirms the presence of low to moderate permeability for the shallow native subsoil that would be considered for the proposed infiltration infrastructure to redirect the precipitation and runoff to the subsurface.

The subject site is located within the Credit River Watershed. The Credit River Watershed covers an area of approximately 1,000 km<sup>2</sup>, extending from the Town of Orangeville in the north to the City of Mississauga and Lake Ontario in south. A review of the local topography and the ground surface elevations at the borehole and monitoring wells shows that the subject site descends towards Trafalgar Road, towards the southeast.

Runoff from the site is expected to drain in southerly and easterly directions. Based on review of the topographic map for the area, and from review of the ground surface elevations at the borehole and monitoring well locations, the elevation relief across the subject site is about 15.0 m.

- **Water Balance Assessment**

The water balance for this proposed infill development site is based on the following equation:

$$P = ET + R + I + \Delta S$$

Where:

- P -- Average Annual Precipitation
- ET -- Evapotranspiration
- R -- Surface Water Runoff
- I -- Infiltration
- $\Delta S$  -- Change in Groundwater Storage, taken as 0

- **Precipitation**

The long-term records (30-year average from 1981 to 2010) for monthly and annual precipitation depths received at the site were adopted from the Environment Canada's Orangeville Station (Climate ID. 6155790), located about 15 km north of the subject site. The 30-year, mean annual precipitation record of 901.50 mm/year was adopted from this station. The 30-year records for average annual, and monthly temperatures were also adopted from this station. The water balance calculations for the pre- and post-developed assessments for the subject site are summarized in the Appendix.

- **Interception**

Based on the review of the SWM Planning and Design Manual (MOECC, 2003), evapotranspiration includes the evaporation from all sources; including; precipitation, water, snow, vegetation and from water droplets on plant surfaces plus the transpiration from plants, not involving water droplets retained on leaves. As such, interception was not included for the current pre- and post-development water balance assessments as it is included in the estimate for evapotranspiration.

- **Groundwater Storage**

Although groundwater storage experiences gains and losses on a short-term basis, the net change in groundwater storage ( $\Delta s$ ) over the long-term is generally zero. For this reason, the change in groundwater storage is shown as zero (0) which has not been included in the water balance calculations.

- **Evapotranspiration**

In general, evapotranspiration (ET) refers to the transfer of water from vegetation and from the soil surface to the atmosphere in the form of water vapour. The term considers evaporation from the soil surface, man-made infrastructure surfaces (asphaltic and concrete roads, and from building roofs), and from the transpiration from plants and trees together because of the difficulties in separating these processes. Potential evapotranspiration (PET) refers to the transfer/loss of water from vegetated surfaces to the atmosphere, under the condition of unlimited water supply.

The actual rate of evapotranspiration (AET) is generally less than PET, under dry conditions (i.e., during the summer season when there is a soil moisture deficit). Variation in water holding capacity, which affects ET, depends on the soil type and rooted vegetation. The

gravelly sand, sandy gravel, silt and sand till, and silty sand surface soil at the site, as revealed from the subsurface drilling program, has been assigned a water holding capacity of -150 mm (Soil and Water Conservation Table 18.2 PP 392 G. Schwab et. al.).

Chart 40 from the Climate of the Great Lakes Basin (Environment Canada 1972) suggests that the PET for the Orangeville EC Weather Station should range from about 558.8 to 609.6 mm/year (22 to 24 in/year). Simulations using the Thornthwaite and Mather model developed by the US Geological Survey (USGS) indicate that the amount of ET (PET) for the subject site ranges from about 526.60 to 530.20 mm/year, which agrees well with the mapped ET values for the general area; therefore, the average AET value of 528.4 mm/year has been applied to the pre- and post-water balance assessments for the subject site.

- **Infiltration and Runoff**

According to the Ministry of the Environment, Conservation and Parks (MECP) Guidance Manual (MECP 1995), a series of infiltration components can be applied to the subject site based on its slope, soil and vegetation coverage. The cumulative value of these sub-components is referred to as the infiltration factor, with the values ranging from 0 to 1. The difference between the value 1 and the infiltration factor is referred to as the runoff factor.

Slope has an influence on both infiltration and runoff. The topography for the subject site is considered flat to gently rolling land, based on its elevation relief, and from a review of available topographic mapping for the area. The elevation relief across the subject site is about 15.0 m.

Surficial soil and vegetation coverage and/or cropping practices also contribute to the infiltration and runoff factors. The subject site is primarily farm field, and is partially wooded and the surficial soil consists mainly of gravelly sand, sandy gravel, silt and sand till, and silty sand. The selected, cumulative infiltration and corresponding runoff factors for the subject site, based on its topography, predominant surface soil and vegetation coverage are provided in Table 1.

The difference between the average annual precipitation and actual evapo-transpiration is termed the water surplus. As mentioned, above, the long-term annual precipitation value of 878.78 mm/year has been adopted for the site. Subtracting the averaged, Thornthwaite and Mather derived AET estimate of 528.4 mm/year from the annual precipitation gives a water surplus estimate of 350.38 mm/year. The site's average annual infiltration depth estimate was calculated by multiplying the cumulative infiltration factor by the water surplus estimate, and the site's runoff was calculated by applying its difference from 1, or 1 minus the cumulative

infiltration factor multiplied by the water surplus estimate. Based on the MECP infiltration factors, a cumulative infiltration factor of 0.70 was considered for the water balance assessment. The average annual depth estimates for infiltration and runoff at the undeveloped site are given in Table 1.

**Table 1 - Summary of Infiltration and Runoff Depth Estimates**

| Land Characteristics                                                    | MECP Infiltration Factors | Water Surplus Estimate (mm/yr.) | Infiltration Estimate (mm/yr.) | Runoff Estimate (mm/yr.)       |
|-------------------------------------------------------------------------|---------------------------|---------------------------------|--------------------------------|--------------------------------|
| Cover: (Grass, pavement)                                                | 0.15                      | <b>350.38</b>                   | $I = 0.70 \times 350.38$       | $R = (1 - 0.70) \times 350.38$ |
| Slope: (Rolling land)                                                   | 0.25                      |                                 |                                |                                |
| Soil: (gravelly sand, sandy gravel, silt and sand till, and silty sand) | 0.3                       |                                 |                                |                                |
| Cumulative Infiltration Factor                                          | <b>0.7</b>                |                                 | <b>245.27</b>                  | <b>105.11</b>                  |

Runoff from impervious surfaces is calculated differently than for pervious soil/ vegetated covered surfaces. As a general rule, the ET for impervious surfaces on an average annualized basis is calculated by taking 10% of the average annual precipitation, while runoff is calculated by taking 90% of the average annual precipitation. There are existing impervious surfaces on the site, prior to site development, consisting of an existing car dealership and its associated paved, asphalt parking area. Based on this approach, the ET and runoff estimates for the site's impervious surfaces, on an average annualized depth basis are 87.88 mm/year and 790.90 mm/year, respectively.

- **Pre-Development Water Balance**

The pre-development water balance for the site is calculated by multiplying the existing site areas by the various, averaged annualized depth estimates for Precipitation, ET, Infiltration and Runoff. The average volumetric water balance estimates for each water balance component are given in Table 2.

**Table 2 - Summary of Pre-Development Volumetric Water Balance Components**

| <b>Pre-Development Site Areas</b>   | <b>Approximate Area Coverage (m<sup>2</sup>)</b> | <b>Precipitation (m<sup>3</sup>/year)</b> | <b>AET (m<sup>3</sup>/year)</b> | <b>Infiltration (m<sup>3</sup>/year)</b> | <b>Runoff (Pervious) (m<sup>3</sup>/year)</b> |
|-------------------------------------|--------------------------------------------------|-------------------------------------------|---------------------------------|------------------------------------------|-----------------------------------------------|
| Existing Pervious Areas (Grass)     | 523,240.00                                       | 459,812.85                                | 276,480.02                      | 128,332.98                               | 54,999.85                                     |
| Existing Impervious Areas (Asphalt) | 110.00                                           | 96.67                                     | 9.67                            | 0.00                                     | 87.00                                         |
| <b>Total Area/Volume</b>            | <b>523,350.00</b>                                | <b>459,909.51</b>                         | <b>276.489.68</b>               | <b>128,332.98</b>                        | <b>55,086.85</b>                              |

The pre-development water balance for the subject site is calculated on an annualized depth basis by dividing the volumetric estimates for each water balance component from above by the total site area. Furthermore, there are existing impervious areas on site, including a commercial building, an associated parking lot and paved areas. The anticipated AET and runoff for the existing impervious areas were estimated by taking 10% of the average annual precipitation after correction for interception, while runoff is calculated by taking 90% of the average annual precipitation. Based on this approach, the depth-based water balance components for the pre-developed site are presented as follows:

$$P (878.78) = ET (528.31) + I (245.21) + R (105.26)$$

- **Post-Development Water Balance**

Based on the data provided by Urbanworks Engineering Corporation indicates that the subject site comprised a total area of 523,350 m<sup>2</sup>. Of this, the developed impervious areas will include the building footprints and paved areas, covering about 47.49% of the developed site area, or an area of about 248,514 m<sup>2</sup>. Pervious developed areas, including landscaped areas, will comprise the remaining 52.51% of the site, or an area of 274,835 m<sup>2</sup>.

The post-development water balance was calculated using the same water balance depth estimate components that were used for the pre-development water balance calculations, i.e., average annual precipitation and average annual ET. After development, with no infiltration through the impervious areas, the depth estimates for runoff and become 90% and 10% of the corrected average annual precipitation, respectively. The estimated post-development water balance volumes are provided in Table 3:

**Table 3 - Summary of Post-Development Volumetric Water Balance Components**

| Post-Development Site Areas       | Area Coverage (m <sup>2</sup> ) | Precipitation (m <sup>3</sup> /year) | AET (Pervious) (m <sup>3</sup> /year) | AET (Impervious) (m <sup>3</sup> /year) | Infiltration (m <sup>3</sup> /year) | Runoff (Pervious) (m <sup>3</sup> /year) | Runoff (Impervious) (m <sup>3</sup> /year) |
|-----------------------------------|---------------------------------|--------------------------------------|---------------------------------------|-----------------------------------------|-------------------------------------|------------------------------------------|--------------------------------------------|
| Pervious Area (505-Mixed Block)   | 1,705.0                         | 1,498.32                             | 900.92                                | 0.00                                    | 418.18                              | 179.22                                   | 0.00                                       |

Based on the volumetric water balance estimates shown in Table 3, the depth-based post-development water balance estimates are presented as follows:

$$P (878.78) = ET (319.22) + I (128.80) + R (430.76)$$

The volumetric comparisons for evapotranspiration, infiltration and runoff between the pre-developed and post-developed site are summarized in Table 4. A review of the findings indicates a decrease of 209.09 mm/year, or 39.58 %, in annual evapo-transpiration, a decrease of 116.41 mm/year, or 47.47 %, in annual infiltration, and a gain in runoff of 325.51 mm/year or 309.24 %.

| Post- Development                                                           | 459,909.51                              | 167,061.37                   | 67,407.44                              | 225,440.70                       |
| Volumetric Change in Pre- and Post-<br>Development Water Balance Parameters | 0.0                                     | -109,428.31                  | -60,925.54                             | + 170,353.85                     |

Notes: -- loss -- gain

The volumetric comparisons in evapotranspiration, infiltration and runoff between the pre-developed and post-developed site are summarized in Table 4. A review of the findings indicates that decreases of 109,428.31 m<sup>3</sup>/year and 60,925.54 m<sup>3</sup>/year are anticipated for ET and infiltration, respectively. An increase of 170,353.85 m<sup>3</sup>/year is expected for runoff at the post-developed site compared with the pre-developed site.

The pre- and post-development water balance calculations for the site are summarized in the attached Appendix.

We trust the above satisfies your present requirements. Should you have any further queries, please feel free to contact this office.

Yours truly,

Unit Hyd Qpeak (cms)= 3.489

PEAK FLOW (cms)= 2.686 (i)  
TIME TO PEAK (hrs)= 12.333

VISUAL OTTHYMO OUTPUT: Hillsburgh Subdivision  
Post-Development Model, 24hr SCS

DATE: December 2023

RUNOFF VOLUME (mm)= 46.328  
TOTAL RAINFALL (mm)= 112.421  
RUNOFF COEFFICIENT = 0.412

(i) PEAK FLOW DOES NOT INCLUDE BASEFLOW IF ANY.

## **APPENDIX D**

### WATER SUPPLY CALCULATIONS

---

## Water Supply Calculation

Project No.: 22-0020ER

### Proposed Subdivision: Hillsburgh

Fire Flow: **76** L/s (Preferred residential fire flow rate as per Town of Erin Standards)

Water Supply Demand: **290** l/capita/day  
Commercial Demand: **28** m3/area(ha)/day

| Building Type | Units or Area (sqm) | Population | Average Day Demand (l/s) |
|---------------|---------------------|------------|--------------------------|
| Residential   | 662 units           | 2976       | 9.99                     |
| Commercial    | 0 sq.m.             | -          | 0.00                     |
| Total         |                     | 2976       | 9.99                     |

#### Notes:

*Residential Population incorporates population estimates for Mixed-use lands*

| Building | Average Day Demand (l/s) | Min. Hour Demand Peaking Factor † | Min. Hour Demand (l/s) | Max. Hour Demand Peaking Factor † | Max. Hour Demand (l/s) | Max. Day Demand Peaking Factor † | Max. Day Demand (l/s) | Max. Demand + Fire Flow (l/s) |
|----------|--------------------------|-----------------------------------|------------------------|-----------------------------------|------------------------|----------------------------------|-----------------------|-------------------------------|
| Total    | 9.99                     | 0.40                              | 4.00                   | 4.13                              | 41.25                  | 2.75                             | 27.47                 | <b>103.47</b>                 |
